

Fluoride harmless, ... good for your teeth??

Fluoride is an industrial waste product and extremely toxic.

Fluoride has been used as rat poison and insecticide.

Fluoride has caused poisonings, some fatal.

Fluoride accumulates inside your body and can cause side effects.

- Fluoride can easily damage the enamel of your teeth if there is too much fluoride in drinking water or if the total intake from various sources is too high. You end up with dental fluorosis of varying degrees. In Germany research found that it is impossible to deliver a controlled dose of fluoride to each house through the public water supplies.
 - Genuine research found that child dental health is not better in fluoridated areas than in non-fluoridated areas of the same social economic background.
 - Promotional research always found that in fluoridated areas the child dental health was much better than in non-fluoridated areas by comparing anonymous teeth ignoring their social economic background.
 - As the social economic background turns out to be the determinant in healthy teeth, it indicates that adequate food intake plus regular daily cleaning and limited sugar and acid (soft drinks, vinegar in salads etc.) intake determine the state of your teeth.
- Water fluoridation is a smoke screen for other issues. Want to know more? Go to www.rag.org.au and also to www.fluoridealert.org
- Support a Statewide ban on water fluoridation. Contact your local Member of Parliament and your local Councillor and tell them what you think of poison in drinking water.
